

1. Users, task and problem

Our app is for university students who spend long periods studying. It should help them record water intake and check their daily progress without losing focus. We want to make logging quick and remind students when they have not recorded a drink for a while. The aim is to support regular hydration habits.

2. Existing solutions: evidence and assumptions

Our initial comparison describes MyWater as focused on hydration data and charts, while Waterllama puts more emphasis on gamification. Our app focuses on one-tap logging, reminders after inactivity and access to information about tap and mineral water.

Evidence: Existing apps provide hydration tracking, but this does not establish demand for our approach.

Assumptions: We think students may find extra logging steps distracting and prefer a simpler interface. We also assume they would use tap-water information and mineral-water comparisons. We have not tested these assumptions with users.

3. User stories and acceptance criteria

1. Quick logging: As a deeply focused student, I want to log a portion of water with one tap so that I can track my intake without breaking concentration.

Acceptance: Tapping "+250 ml" immediately updates daily progress. The app saves the entry locally and retains it after a restart.

2. Reminders: As a student in a flow state, I want a reminder only after two hours without logging water so that I avoid unnecessary alerts.

Acceptance: Each entry resets the two-hour reminder. The app requests notification permission. If permission is denied, tracking still works and Settings explains how to enable reminders.

3. Tap-water information: As an eco-conscious student, I want to check tap-water quality in my city so that I can decide whether to refill my bottle.

Acceptance: A city search displays loading, results or an error. Without connectivity, the app shows "No connection" and does not crash. We still need to confirm a suitable data source.

4. MVP and boundaries

The main journey is to open the tracker, log water, check updated progress and return to log another drink after a reminder.

The MVP has four screens:

- Tracker: daily progress and a "+250 ml" button.
- Water Checker: city search and tap-water information.
- Mineral Waters: a short list of waters and their properties.
- Settings: daily goal, notification status and local-data reset.

Outside scope: accounts, cloud synchronisation, other drink types, avatars, interactive refill maps, historical charts and personalised mineral-water recommendations.

5. Reviewing our assumptions

An AI consultation challenged whether a refill-station map would fit the MVP. We dropped the map and chose a simpler city search. We still need to verify that suitable water-quality data is available.

AI acknowledgement: We used ChatGPT to discuss scope assumptions and improve the wording and formatting of this brief.
